ABSTRACT

Systemic lupus erythematosus (SLE) is an autoimmune disease that may be associated to high morbidity and mortality. Disease course is variable and unpredictable and although the prognosis and survival of these patients has dramatically improved, treatment of severe multiorgan organic affection in this condition remains a therapeutic challenge. Since B lymphocytes have an important role in the pathogenesis of SLE, it is expected that the targeting of these cells exerts a significant therapeutic effect in SLE patients with severe multiorgan manifestations. In an open clinical trial, we have explored the therapeutic potential of Rituximab (an anti-CD20 monoclonal antibody) administration in SLE patients with severe nephritis (n = 22) or neuropsychiatric manifestations (n = 6) or massive pulmonary hemorrhage (n = 3). In most cases, we observed significant improvement in both clinical and laboratory parameters, with good tolerance and few side effects. Thus, patients with severe lupus nephritis showed improvement in disease activity (MEX-SLEDAI index) with a significant reduction (p < 0.05), as well as proteinuria in most of them (from 3.710 g/L to 1.786 g/L, p < 0.05); patients with serious neurologic involvement had complete remission of their manifestations; but those with pulmonary massive hemorrhage did not have any response. Rituximab could have an important therapeutic potential in severe SLE, and that it is necessary to carry out a controlled blinded clinical trial to further support this point.

RESUMEN

El lupus eritematoso sistémico es un padecimiento con bases autoinmunes que puede asociarse a elevada morbilidad y mortalidad. El curso es variable e impredecible, y aunque el pronóstico y la supervivencia de los pacientes han mejorado de forma significativa, la afectación multiorgánica puede representar un reto terapéutico. Dado que los linfocitos B tienen un papel protagónico en esta enfermedad, es esperable que como blanco del tratamiento, pueda resultar en un efecto terapéutico significativo en el lupus eritematoso. En este estudio clínico abierto, exploramos el potencial terapéutico de la administración de rituximab (un anticuerpo monoclonal) en pacientes con lupus grave: nefropatía (n = 22), manifestaciones neuropsiquiátricas (n = 6) o hemorragia pulmonar masiva (n = 3). En la mayoría de los pacientes, observamos mejoría significativa, tanto en los parámetros clínicos como de laboratorio y gabinete, con buena tolerancia y pocos eventos adversos. De tal manera que los pacientes con nefropatía lúpica grave mostraron disminución significativa de la actividad de la enfermedad (MEX-SLEDAI) (p < 0.05), también en los niveles de proteinuria (de 3.710 g/L a 1.786 g/L, p < 0.05); los pacientes con afectación neurológica grave, al igual que los del grupo con hemorragia pulmonar masiva, no observamos respuesta alguna. Rituximab pudiera tener un importante potencial terapéutico en los pacientes con lupus grave; es necesario el realizar un estudio clínico doble ciego controlado a largo plazo que ratifique nuestros hallazgos.

Introduction

Systemic lupus erythematosus (SLE) is a multiorgan auto-immune disease with heterogeneous clinical manifestations and unpredictable disease course. Although the prognosis and survival of SLE patients have dramatically improved, the treatment of severe multiorgan affection remains as a therapeutic
Severe nephritis, transverse myelitis and massive pulmonary hemorrhage are three of the most serious manifestations of SLE. These conditions are associated with high morbidity and mortality, including those events that are consequence of the immunosuppressive therapy.1-4

Different abnormalities of T and B lymphocytes are involved in the pathogenesis of SLE.5-9 B lymphocytes synthesize several cytokines involved in the pathogenesis of SLE (including IL-10), have an important role as antigen presenting cells, and are the source of the different auto-antibodies detected in these patients.10,11 Therefore, B lymphocytes have been considered as a good therapeutic target in SLE.12,13 Rituximab is a chimeric monoclonal antibody, with human IgG1 and kappa light chain constant domains, and mouse variable regions from a mouse hybridoma producing an anti-human CD20 antibody.14,15 CD20 is expressed by immature and mature B lymphocytes, but not by early B cell precursors or plasma cells. This biological agent causes B-cell depletion in vivo, inducing complement and antibody dependent cellular toxicity as well as antibody mediated apoptosis.16 Interestingly, administration of Rituximab does not seem to have a significant effect on serum immunoglobulin levels, but its administration could be associated with diminution of autoantibody levels.17,18

There are different preliminary studies on the therapy of SLE and other autoimmune diseases with Rituximab.19-24 In this regard, it has been reported that this biological agent seems to induce clinical improvement and diminution of the abnormalities found in B lymphocytes in patients with this condition.25-28 In addition, we have previously found that the addition of Rituximab to the immunosuppressive therapy of patients with refractory lupus nephritis resulted in a marked improvement in both, renal function and disease activity.29 Furthermore, it has been reported that Rituximab therapy of SLE patients is associated with diminution of activation markers of T lymphocytes, including the expression of CD40L, as well as with a significant effect on the levels and function of T regulatory cells, and the induction of T cell apoptosis.29,30

In an open clinical trial we have explored the possible therapeutic effect of Rituximab in SLE patients with severe manifestations, specifically with severe nephritis or CNS affection or massive pulmonary hemorrhage. Our data strongly suggest that Rituximab exerts an important beneficial effect in most of these patients. In our previous report we emphasize that patients with severe nephritis (type IV: 18, type III and type V: 2) had improvement of levels and function of T regulatory cells and induction of T cell apoptosis, immunological facts which could explain the clinical response to diverse dosages of rituximab in spite do not have increased steroids therapy or do not have used steroids. In this paper we show our clinical data of this group of patients, besides two additional groups, one of them with very severe nephritis (type IV: 18), type III and type V (2); all of them under DMARD’s therapy and most with variable doses of steroids, with persistent activity, through proteinuria, urinary red or white cells or casts. Following was made with creatinine levels, diay proteinuria and creatinin clearance. Patients received Rituximab 500 to 1000 mg once or twice, at 2 week intervals, and the therapeutic response was evaluated by clinical and laboratory parameters. The rituximab dosage varied because economic limitation; previously we have used low dosage of rituximab in diverse autoimmune diseases (rheumatoid arthritis, dermatomyositis, and systemic lupus erythematosus) with similar results (B cell depletion, immune-regulatory effects, and clinical response) of those reported with conventional approved doses. All patients were pretreated with dexametasone (8 mg i.v.) or prednisone, (40 mg., p.o.), and loratadine (10 mg p.o.). Infusion of Rituximab started slowly (15 drops/min), increasing each 20 min. Because patients with renal involvement were under immunosuppressive therapy (most of them with 2 or more DMARD’s) when occurred their renal exacerbation or relapse, we decided that did not necessary to increase steroid dosage and maintain without this drug in 6 of them. We included here, two other patient groups, one with severe central neurologic involvement and the other one with acute massive pulmonary hemorrhage, and all of these patients received high doses of methylprednisolone together. Massive pulmonary hemorrhage was defined characteristically with severe acute respiratory failure with diminution of 3 or more grams of haemoglobin without any other potential responsible causes; so, three patients with massive pulmonary hemorrhage diagnosis were treated with 1 g of rituximab, and additionally received methylprednisolone (at least 1 g/day for 4 days), cyclophosphamide (500 mg/m²), and azathioprine (150 mg/day) or methotrexate (15 mg), beside diay hemodialysis. When data of an allergic reaction were collected, infusion was stopped, and hydrocortisone was administered (100 mg i.v.). In these cases, after a careful clinical evaluation, Rituximab infusion was re-started, upon the continuous monitoring of these patients.

To evaluate differences from basal and 60 days post-rituximab therapy, we used decrptive statistical analysis and comparison media values with t student.

Results

We have previously reported that the addition of Rituximab to the immunosuppressive therapy of patients with refractory lupus nephritis is associated with significant improvement in different clinical and laboratory parameters.29 All, except two of them had B cell depletion with 500 to 2 g of rituximab. All patients were under intensive immune-regulatory therapy and we decided that in spite renal activity the dose of glucocorticoids remained unchanged during the study, and in six cases whose did not are with steroid therapy, these drugs were not administered, but the patients continued with their DMARD’s therapy.

In the Table, we show the demographic characteristics of our patients with SLE and severe glomerulonephritis. As previously reported in these patients, Rituximab therapy induced a significant improvement in different clinical parameters in most of them, in spite the administration of only 1.0 g of this biologic agent. It is worth mentioning that in six of these patients, no glucocorticoids additionally to those associated to rituximab infusion were administered and that in the rest of the group the dose of these anti-inflammatory drugs remained unchanged. In these patients with severe glomerulonephritis, the disease activity (MEX-SLEDAI index) significantly diminished (p <0.05) as well as proteinuria, in most of them (from 3.710 g/L to 1.786 g/L, p < 0.05). Diminution of proteinuria occurred as early as at day 8 after the
The first infusion of Rituximab. Creatinine clearance increased in 72% of patients, but this variation did not reach statistical significance (73 to 86 ml/1.73 m²), neither the apparent diminution of serum creatinine levels (0.97 to 0.78 mg/dl).

Five of our patients showed a complete remission of renal disease (defined as normal renal function, inactive sediment and proteinuria < 500 mg/L), and seven patients showed a partial renal response (stable renal function, inactive sediment and diminution of proteinuria > 50%). Six additional patients exhibited improvement in one or several renal parameters, however bided improvement in one or several renal parameters, however dimution of proteinuria renal response (stable renal function, inactive sediment and diminution of proteinuria).

As we mentioned previously, most of patients with severe glomerulonephritis (20/22) that received Rituximab had evidence of B cell depletion and only one of them had a severe and fatal infection with massive pulmonary haemorrhage associated to pulmonary histoplasmosis and arterial coronary mucormycosis. This patient was under mofetil mycophenolate therapy, and had an episode of diabetic ketoacidosis.

In our group of six SLE patients with severe central nervous system (Table 2) disease we observed an excellent response to Rituximab therapy. In all cases no permanent damage or disability was observed, including in the two patients with transverse myelitis, one with meningo-encephalitis, one with cerebellar syndrome, one with hemorrhagic stroke and one with severe choroathetotic movements. Patients with transverse myelitis received rituximab in their second (case 1) and third (case 2) episodes, and in this last episode of the second patient who had sensitive level and distal dysesthesias, we decided do not use mofetil mycophenolate therapy, and had an episode of diabetic ketoacidosis.

We realized MRI studies only in their 1st myelitis presentation, and in both cases, were normal. Patient 4, had MRI totally normal, in fact she was well until 3 months after her had received rituximab 1 g, when she presented again a cerebellar affection with ataxia and a new MRI study was also normal; she was treated with rituximab 1 g and mPDN pulses with complete resolution 15 days after and she continue healthy. The other 3 patients have had MRI abnormalities; in Fig. 1, we show some of images of MR related to patient 3, who achieve complete clinical remission and IRM normal, study that was taken 2 months after were treated with rituximab 1g; he is healthy 3 years after and is being treated with hidroxi-cloroquine and siimastatine.

The three female patients with massive pulmonary hemorrhage that received Rituximab had a fatal course despite the concomitant administration of mPDN pulses (average 50 mg/dl), combined with cytotoxic drugs and at least 3 hemodialysis sessions. Patients received one cycle of cyclophosphamide 500 mg/m². Probably in these cases, rituximab was not a good therapy because patients died in a few days after they started with their clinical manifestations of acute severe respiratory failure. All patients had renal, dermatologic and rheumatologic affectations, besides to have positive antinuclear antibodies and two of them hypocomplementemia.

### Clinical examples

1. A nine years old boy, with asymmetric oligoarthritis, a papular skin rash, abdominal pain, and evidence of renel disease was admitted to the emergency room. Schönlein-Henoch syndrome diagnosis was established, and prednison 0.5 mg/kg/day improved his clinical manifestations. However, a renal biopsy showed diffuse and generalized glomerulonephritis, with crescents in 3/15 glomerulus, and immune granular deposits of IgG, IgA, IgM, C3 and C1q. An aggressive immunosuppressive therapy was started with prednison 1.0 mg/kg/day, cyclophosphamide, azathioprine and cyclosporine, but no favorable response was observed with an enhanced proteinuria (1.25 g/L), heavy erythrocyturia, numerous casts, and a significant diminution in creatinine clearance (60 ml/min). Rituximab
(0.5 g, two infusions, at days 1 and 15) was added to his therapy and a significant improvement in most clinical (asymptomatic) and laboratory (proteinuria of 425 mg/L, creatinine clearance of 85 ml/min) parameters was observed. However, an active urinary sediment persists 18 months after Rituximab therapy, and actually his therapy is with mycophenolate, low doses of steroids, methotrexate, statins, angiotensin inhibitors and vitamin D. The interest to report this patient is because Schönlein-Henoch purpura is a rare SLE presentation, but in spite adequate therapy persist with glomerulonephritis activity.

2. A 21 years old female with diagnosis of SLE, and under cytotoxic therapy because type IV lupus nephritis was admitted because photosensitivity, facial erythema, polyarthralgias, myalgias, transitory pleuritic chest pain, and fever, with an active urinary sediment and 3.25 g/L of proteinuria. One week later of rituximab therapy, proteinuria fall to 1.75 g/L, and no casts or erythrocytes were detected in a new urine
Our findings further support the previous reports on the beneficial effect of Rituximab administration in patients with SLE, mainly in patients with severe and refractory nephropathy as well as those with CNS disease.23,34–36 However, this biological agent does not seem to have a role in the therapy of the massive pulmonary hemorrhage associated to SLE, at least for the treatment of the acute, severe manifestations of this condition, potentially fatal in a few days, episodes of short time that may be do not permit the action of immune therapy including rituximab.

Most of our patients with severe lupus nephropathy had a dramatic improvement after Rituximab administration. However, two patients showed progression to renal failure, one of them died and the other one is in hemodialysis. One of these patients had serious mixed acidosis conditioned by uncontrolled diabetes mellitus and an undetected infectious process. At necropsy, two fungal infections were detected, histoplasmosis in the lungs, and mucormycosis in a coronary artery. However, according to our study, Rituximab, although is a potent inducer of B cell depletion, and show a strong anti-inflammatory/immunosuppressive effect, its administration seems to be rarely associated to serious adverse events, even when is combined with different immunosuppressive drugs. In addition, Rituximab seems to maintain its therapeutic effect for months or even years, as we describe here, and it has been reported by others, but frequently because relapses in the cases of severe lupus nephritis we should consider a new course of this B cell depleting therapy.23–30,37

We consider that it would be of interest to assess the efficacy of Rituximab as a single immunosuppressive agent for the therapy of severe SLE. We think that it is possible that, at least in some cases, Rituximab alone would be able to exert a significant beneficial effect, and even, in some patients, to induce disease remission. In this regard, it is worth mentioning that in six patients of our study, the beneficial effect of Rituximab was exerted without the concomitant administration of glucocorticoids. In this regard, these data suggest that glucocorticoids could be not as important in Rituximab therapy of autoimmune diseases as previously thought, in particular when patients are being treated with immune-regulatory agents, and additionally if we do not increase or prescribe steroids, we will have less immunosuppressive effects associated to this therapy, but with similar efficacy. Finally, it is important to keep in mind that we performed an open preliminary trial and that our results on the apparent beneficial effect of Rituximab in severe SLE should be validated through a large controlled and blinded study.
