Background: Imaging may be useful for monitoring response to therapy. Within the OMERACT proposal for the core set domains for outcome measures in chronic gout, serum urate levels, recurrence of gouty flares, tophus regression, and joint damage imaging have been included, among other proposed issues. Objectives: To perform a systematic literature review of the usefulness of magnetic resonance imaging (MRI) and ultrasound (US) on assessment of treatment response in patients with gout. Methods: MEDLINE, EMBASE, Cochrane Library (up to February 2012), and abstracts presented at the 2010 and 2011 meetings of the American College of Rheumatology and European League Against Rheumatism were searched for treatment studies of any duration and therapeutic options, examining the ability of MRI/US to assess treatment response in gouty patients. Meta-analyses, systematic reviews, randomized clinical trials, cohort and case-control studies and validation studies were included. Quality was appraised using validated scales. Results: There were only 3 US published studies in the literature that analyzed US utility on assessment of response to treatment in patients with gout. All of them were prospective case studies with a small number of patients and they were reviewed in a detailed manner. A total of 36 patients with gout were examined with US. All of them had a baseline serum urate >6 mg/dL. US features of gout (double contour sign, hyperechoic spots in synovial fluid, hyperechoic cloudy areas, tophus diameter and volume) achieved significant reduction in patients who reached the objective of uricemia <6 mg/dL in all the studies; however, patients in whom levels did not drop below 6 mg/dL had no change of US features of gout. Other parameters evaluated in one study included ESR, CRP, number of tender joints (TRN), number of swollen joints, and pain score (SP). All of them decreased with uricemia reduction, but only TRN and SP were statistically significant. No data were found on the value of MRI on treatment response assessment in patients with gout. Conclusions: The improvement in ultrasound features shows concurrent validity with uric acid reduction. According to the published evidence, US can be a useful tool for monitoring treatment of gouty patients, although more research is needed. The value of MRI on treatment response assessment in patients with gout remains to be determined.

Revisión sistemática sobre el valor de la ecografía y la resonancia magnética nuclear musculosquelécticas en la evaluación de la respuesta al tratamiento en la gota

R E S U M E N

Objetivos: Evaluar sistemáticamente la evidencia publicada en relación con la utilidad de la ecografía y de la resonancia magnética nuclear (RMN) en la evaluación de la respuesta al tratamiento en pacientes con artritis por depósito de cristales de urato monosódico.

Métodos: Revisión sistemática. Se definió una estrategia de búsqueda bibliográfica sensible en MEDLINE (desde 1960), EMBASE (desde 1980) y Cochrane Library (Central) y búsqueda manual en lo publicado en congresos internacionales (EULAR, ACR), seleccionando estudios que evaluasen la respuesta al tratamiento de los pacientes con gota (AINS, hipouricémicas, etc., independientemente del tipo, de la dosis y de la duración del tratamiento e independientemente del criterio seleccionado para el diagnóstico, el tipo y el número de articulaciones afectadas) mediante pruebas de imagen (ecografía y/o RMN). Se seleccionaron metaanálisis, revisiones sistemáticas, ensayos clínicos, cohortes de calidad y estudios de validación. 

Resultados: Los estudios incluidos fueron 3 series de casos, de diseño prospectivo, en los que se analizó un total de 36 pacientes con artritis gotosa y en los que se evaluó la respuesta al tratamiento hipouricémico mediante ecografía. No hubo ningún estudio que analizara la respuesta al tratamiento hipouricémico con RMN. Todos los pacientes incluidos tenían valores basales de uricemia por encima de las recomendaciones EULAR. La mejoría en los hallazgos ecográficos se correlacionó con la reducción de los valores séricos de ácido úrico en todos los estudios.

Conclusiones: El uso de la ecografía parece útil en la evaluación de la respuesta al tratamiento hipouricémico en los pacientes con artritis gotosa (nivel de evidencia 3a; grado de recomendación B). Actualmente no se dispone de ninguna evidencia para analizar la utilidad de la RMN en la evaluación del tratamiento de los pacientes con artritis gotosa.

evaluating the sonographic “double contour” sign, the Doppler signal was analyzed, as was the presence or absence of hyperechoic spots in the synovial fluid and the presence or not of hyperechoic “cottony spots”. The main features of the articles included in this systematic review are shown in Table 1.

Description of Results of Included Articles

All patients had baseline serum uric acid above the EULAR recommendations (>6 mg/dL) in the study by Thiele and Schlesinger, 10 14 mg/dL in the Perez-Ruiz et al. study 9 and 17 mg/dL in the Peiteado et al. paper 11), and therefore, in the 2 studies in which the ultrasound “double contour” sign 9,11 was assessed, this was present at baseline in all patients. In both studies, the improvement in ultrasound findings correlated with the reduction of serum uric acid. The double contour sign is significantly reduced and even disappeared in patients who achieved the target (uricemia ≤6 mg/dL), but no changes occurred in patients whose serum uric acid values did not decrease below this figure. Other activity parameters evaluated in the study by Peiteado et al. 11 decreased with good control of uric acid levels but did not reach statistical significance: ESR, CRP, number of swollen joints and doppler ultrasound signal.

In the study by Perez-Ruiz et al., 9 wherein the changes detected by ultrasound regarding the size and volume of tophi were analyzed, it was observed that most of the tophi had changes in the maximum diameter or volume, and this occurred in patients who had an adequate control of serum uric acid. Thus, in patients with uric acid below 6 mg/dL, 68% had a reduction of tophi below the minimum detectable difference, while only 10% of patients with tophi and a uric concentration above 6 mg/dL had a significant reduction. In addition, there was an inverse correlation between the reduction of the maximum diameter, transverse diameter and mean tophi volume and serum uric acid concentration during hypouricemic treatment.

No study reported any adverse event in relation to the use of ultrasound.

Excluded Studies

The exclusion table is not shown, since all selected articles were included in detail.

Discussion

In this systematic review of the literature we analyzed the value of ultrasound and MRI in the evaluation of treatment response in patients with gouty arthritis. To achieve this goal, we conducted an extensive search on the main bibliographic databases available, as described in the Materials and Methods section. After detailed analysis of the selected studies, only three studies were included that examined the utility of ultrasound to evaluate the response to treatment, 2 published in international journals and one 9,10 presented solely as a poster at EULAR. 11 All were case series conducted at a single center with a small number of patients (level of evidence 3a on the Oxford quality scale). There were no studies evaluating the response to treatment with hypouricemic drugs using MRI. It represents one of the main limitations of this review, which should be kept in mind when evaluating the findings.

Regarding patients studied, 9,10,11 all had gouty arthritis diagnosed by detecting MSU crystals in the synovial fluid with a polarized light microscope, all had baseline uricemia values above EULAR recommendations (>6 mg/dL) and in the 2 studies analyzed 9,10 all patients had a baseline ultrasound “double contour” sign (deposits of uric acid crystals in hyaline cartilage, which increases the cartilage surface interface thickness reaching something similar to the

* Quality was assessed according to the Oxford scale.
subchondral bone). Determinations of uric acid at baseline and at each follow-up visit were performed, and hypouricemic treatment was adjusted based on the EULAR recommendations.\(^5\)\(^6\)

Although the included studies were heterogeneous in terms of the clinical and sonographic variables collected, all of them showed the reduction of serum uric acid to be significantly correlated with improved ultrasound findings: decline and even disappearance of the “double contour” sign in patients with uric acid below 6 mg/dL in the studies by Thiele and Schlesinger\(^10\) and Peiteado et al.\(^11\) and reduction of the maximum transverse diameter and volume of tophi in the study by Perez-Ruiz et al.\(^9\)

Ultrasound has been shown to be an imaging technique sensitive to change for inflammatory activity present in patients with different inflammatory rheumatic diseases, including gout, allowing us to objectify synovitis or tendinitis and quantify the Doppler signal intensity. It has also proven to be more sensitive than plain X-rays in the early detection of bone erosions, displaying the structural damage to tendons and entheses and being capable of detecting tophi < cm 1, which are difficult to detect even by MRI.\(^12\)\(^-\)\(^16\)

Although based on what has been commented previously it seems logical that ultrasound could be a useful technique in the evaluation of response to treatment with hypouricemic agents in patients with gout, there is little information published in the literature to analyze this aspect. With the studies currently available, we can only say that ultrasound may be useful for evaluating the response to hypouricemic treatment in patients with gout with a 3a level of evidence and a B degree of recommendation. However, taking into account the limitations encountered in this systematic review, we believe that larger studies (randomized clinical trials, cohorts, etc.) will be needed to confirm these results.

As for MRI, although published studies in the literature have shown its reliability in the detection and measurement of tophi, there is currently no evidence to evaluate its usefulness in the treatment response of patients with gout.

**Ethical Responsibilities**

**Protection of persons and animals.** The authors state that no experiments were performed on persons or animals for this study.

**Data confidentiality.** The authors state that they have followed their workplace protocols regarding the publication of patient data and all patients included in the study have received enough information and have given their written informed consent to participate in the study.

**Right to privacy and informed consent.** The authors state that they have obtained informed consent from patients and/or subjects referred to in this article. This document is in the possession of the corresponding author.

**Conflict of Interest**

The authors declare no conflicts of interest.
